

Computer Homework 7 Non-ideal Capacitor

A parallel-plate capacitor shown in the figure, has an infinite length in z-axis. The distance between the plates is $d = 1$ mm, the width of both plates is $L = 4$ mm, and the voltage is 100 Volt on the top plate and -100 Volt on the bottom. If we want to consider the edge effect of the non-ideal capacitor, we need to calculate numerically the total charge on each plate per meter length in z-axis in order to obtain the capacitance value per meter length in z-axis.

From General Physics course, we already know that anywhere $\vec{E} = -(\frac{\partial V}{\partial x}\hat{x} + \frac{\partial V}{\partial y}\hat{y} + \frac{\partial V}{\partial z}\hat{z})$. Now we choose an infinitesimal cube of volume $dxdydz$. In the two faces perpendicular to the x-axis, we have the net electric flux for the two faces as

$$E_x(x+dx)dydz - E_x(x)dydz = \left(\frac{\partial E_x}{\partial x}dx\right)dydz = \frac{\partial E_x}{\partial x}dV.$$

Similarly, the net flux for the two faces perpendicular to the y-axis is $\frac{\partial E_y}{\partial y}dV$,

and the two faces to z-axis is $\frac{\partial E_z}{\partial z}dV$. Therefore, the total flux around the cube is $\phi = (\frac{\partial E_x}{\partial x} + \frac{\partial E_y}{\partial y} + \frac{\partial E_z}{\partial z})dV$.

If no charge is inside this cube, by Gauss' Law, $\phi = \frac{q}{\epsilon_0} = 0$, meaning $\frac{\partial E_x}{\partial x} + \frac{\partial E_y}{\partial y} + \frac{\partial E_z}{\partial z} = 0$. With

$\vec{E} = -(\frac{\partial V}{\partial x}\hat{x} + \frac{\partial V}{\partial y}\hat{y} + \frac{\partial V}{\partial z}\hat{z}) = E_x\hat{x} + E_y\hat{y} + E_z\hat{z}$, it then becomes $\frac{\partial^2 V}{\partial x^2} + \frac{\partial^2 V}{\partial y^2} + \frac{\partial^2 V}{\partial z^2} = 0$, which is called a Laplace's Equation and is usually written as $\nabla^2 V = 0$. The operator ∇^2 is called a Laplacian operator.

Since in this problem, there is no charge variation along the z-axis, by symmetry $E_z = 0$ and $\frac{\partial^2 V}{\partial z^2} = 0$

everywhere. We can reduce the 3-dimensional Laplace's Equation to 2-dimensional, $\frac{\partial^2 V}{\partial x^2} + \frac{\partial^2 V}{\partial y^2} = 0$.

With the condition that at the position of the top and bottom plates $V = +100$ V and -100 V respectively, we can try to solve this Laplacian problem by the numerical Laplacian solver. The simplest numerical Laplacian solver is illustrated as the following and starts from the Taylor's expansion:

$$V(x+h, y) \approx V(x, y) + h\frac{\partial V}{\partial x} + \frac{h^2}{2}\frac{\partial^2 V}{\partial x^2}; \quad V(x, y+h) \approx V(x, y) + h\frac{\partial V}{\partial y} + \frac{h^2}{2}\frac{\partial^2 V}{\partial y^2};$$

$$V(x-h, y) \approx V(x, y) - h\frac{\partial V}{\partial x} + \frac{h^2}{2}\frac{\partial^2 V}{\partial x^2}; \quad V(x, y-h) \approx V(x, y) - h\frac{\partial V}{\partial y} + \frac{h^2}{2}\frac{\partial^2 V}{\partial y^2}.$$

We add the above four equations and will obtain

$$V(x, y) = \frac{1}{4}[V(x+h, y) + V(x-h, y) + V(x, y+h) + V(x, y-h)] \quad (*1) \quad \text{because } \frac{\partial^2 V}{\partial x^2} + \frac{\partial^2 V}{\partial y^2} = 0.$$

Therefore, the potential at each grid-point is simply the mean value of its nearest neighbors. To find the solution one must fix the values of the grid-points on the boundaries or on the positions according to the required conditions and then iterate the potentials until successive results agree each other to within the desired tolerance. This usually can be done with many enough iterations.

In the following program, (1) we use the finite-difference methods for the grid points on the region of interest and set the potential on the top and bottom plates to be $\pm 100V$, (2) we solve the 2-D Laplace's equation at each grid-point, (3) by taking the gradient of the potential, we obtain the electric field on x-y plane, (4) by numerically integrating the Gauss surface we obtain the total charge on the capacitor, and (5) dividing the total charge by the voltage difference we obtain the capacitance. Your job is to complete the template code for (2), (4), and (5) and compare the value of (5) to the value of an ideal parallel-plate capacitor. (Note: You can change this program easily to calculate the capacitance of a rectangular parallel-plate capacitor, i.e. the length in z is not infinite)
